

LVEF and age adjusted Cox survival analysis. The adjusted Cox model demonstrated that patients in the LDG were 39% more likely to die during the follow-up period compared with those in the non-LDG (95% CI 1.31-1.48, $p<0.001$). **CI**: confidence interval, **LDG**: LVEF discrepancy group ($AI_{LVEF} < Reported_{LVEF}$), **LVEF**: left ventricular ejection fraction.
